ABSTRACT: An oxidative C–H coupling is described for medium-ring synthesis.

Transition-metal-catalyzed oxidative C–H coupling offers a highly efficient approach to biaryl synthesis. Using two C–H bonds as coupling partners, no pre-functionalization is required and the reaction can, in principle, afford minimal waste products. The field has undergone rapid growth in recent years, with a number of impressive intermolecular cross-couplings being developed. The intramolecular variant, by contrast, has not been widely investigated. Seminal work in the 1970s established the reaction for five-membered, fully aromatic systems such as carbazoles and dibenzofurans, but applications to alternative ring systems are rare (Figure 1). We reasoned that dehydrogenative coupling for the synthesis of medium-ring-containing biaryls would represent a powerful approach to these compounds, which are often difficult to access by classical routes. These challenges are particularly relevant to medicinal chemistry; despite the plethora of medium-ring structures found in biologically active natural products, seven-, eight-, and nine-membered rings remain rare in drug molecules (Figure 1).

We chose to study the indole system, given its widespread occurrence in biologically active compounds. A screen of N-alkylated indoles identified compounds of general structure 1, containing an electron-withdrawing group (EWG) at the indole 3-position, as potential substrates for dehydrogenative seven-membered ring formation. A catalyst optimization study (Supporting Information) established that catalytic Pd(OAc)₂ in the presence of excess Cu(OAc)₂, using DMA as solvent, was effective for C–C bond formation, with the parent structure 2a being formed in 77% yield (Chart 1). With these conditions in hand, we examined their generality for seven-membered ring formation. A range of indole substrates corresponding to general structure 1 were prepared, wherein the substituent pattern, heteroatom substitution, and EWG at the indole 3-position were all varied.

We were pleased to see that the reaction conditions proved general, delivering a variety of medium-ring annulated indoles in good to excellent yield. Aromatic rings containing p-MeO and p-CF₃ groups were good substrates for the reaction, affording indoles 2b and 2c in 60 and 80% yields, respectively. A substrate containing a m-fluoro aromatic ring was prepared to gain some insight into the mechanism of the reaction. Medium-ring biaryl 2d was formed as the major regioisomer (63% overall yield, 4:1 dr), i.e., the more acidic hydrogen atom underwent reaction, suggesting a base-assisted palladation pathway was operating in the reaction mechanism (vide infra). Incorporation of heteroatoms into the tethering chain was possible, with the three oxazapane derivatives 2e, 2f, and 2g all formed in good yield. Interestingly, no five-membered ring products from C–H activation at the benzylic position were observed for substrates 2e and 2f, despite the susceptibility of benzyl ethers to oxidation.

The reaction was very effective for the synthesis of symmetrical bisindole 4a, synthesized in 91% yield from C2 oxidative coupling of the symmetrical precursor. We could likewise use both benzimidazole and pyrazole C–H bonds as participants in the reaction to form the highly functionalized biheteroaryls 4b, 4c, and 4d in good yields.

Following the success of the reaction for seven-membered ring synthesis, we applied the same approach to the more challenging...
eight-membered-ring targets (Chart 3). Eight-membered rings are generally the most difficult of the medium rings to form, due to energetically unfavorable transannular and torsional strain effects in ring-closing reactions.\textsuperscript{10} These difficulties were manifest in our initial attempts at oxidative cyclization of substrate 5a, which were unsuccessful under a range of conditions. We reasoned that the replacement of a methylene in the tethering chain with a heteroatom might serve to both reduce transannular strain and provide a stabilizing interaction with the presumed Pd(II) intermediate in the reaction (structure 7).\textsuperscript{11} We were pleased to see that incorporation of a dibenzylamine group (5b) into the substrate proved a success, providing eight-membered diazocane derivative 6b in 60% yield. This reaction was extended to a small range of examples: Products 6b and 6c arise from dibenzylamine derivatives containing four identical sites for aromatic C–H activation. Interestingly, 6d was isolated as a 1:1 mixture of diastereoisomers, suggesting hindered rotation around the biaryl axis. The dibenzyl motif allowed us to set up a competition experiment to probe the mechanism, using electron-rich (p-OMe) and electron-poor (p-F) benzyl groups in the same substrate. Compounds 6e and 6f were isolated in 62% combined...
yield in the ratio 1.6:1. The more acidic C—H bond on the fluoro-substituted arene is preferentially activated, although the selectivity is reduced relative to that seen with the previous seven-membered systems (Chart 1, 2d and 2d').

A preliminary picture of the reaction mechanism is set out in Scheme 1. Palladation of the indole at C2 forms complex I, an intermediate that could be successfully trapped with methyl acrylate in a Fujiwara—Moritani-type process 12 to give ester 8 (Supporting Information). In the normal course of reaction, I then undergoes a concerted metalation—deprotonation (CMD) 13 step to afford intermediate II. An alternative electrophilic palladation mechanism is unlikely here due to the observed selectivities for electron-poor sites in competition experiments (2d in Chart 1 and 6g/6f in Chart 3). 14 In addition, an intramolecular kinetic isotope effect (KIE) study on substrate 1g-H/D gave a value of kH/kD = 3.3, in line with literature reports of C—H activation via CMD mechanisms. 4c,15,16 Reductive elimination then produces the medium-ring products, along with Pd(0) which is reoxidized by the excess Cu(II) in the reaction.

In conclusion, we have shown for the first time that intramolecular oxidative C—H coupling is an effective strategy for synthesizing medium-ring compounds. The reaction is tolerant of a rich array of functional groups, forming annulated heterocycles for application as versatile scaffolds in medicinal chemistry. 17,18 Previous routes to these medium-ring-containing indoles have featured lengthy, multistep routes; our approach is rapid, using a simple catalyst system and should be amenable to a broad range of further applications in medium-ring heterocycle synthesis.
